The invention relates to a non-naturally occurring gene therapy vector, comprising an inner shell having a core complex containing a nucleic acid and at least one complex forming reagent. The vectors are stable having a nimproved outer steric layer that provides enhanced target specificity, in vivo and colloidal stability. The vectors are relatively homogeneous and comprise chemically defined species. The vectors demonstrate improved call entry and intracellular trafficking, permitting enhanced nucleic acid therapeutic activity such as gene expression. The present sequence is that of the peptide K14 Fuso, comprising a fusogenic peptide derived from influenza haemagglutinin and peptide K14, useful in the preparation
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             The present invention relates to compositions of modified soluble protein antigens capable of eliciting an enhanced in vivo cytotoxic T cell (CTL) response i.e. a major histocompatability complex (MHC) class I molecule response. The protein antigen is modified by the covalent addition of a peptide sequence which facilitate entry of the antigen into antigen presenting cells (APCs). The present sequence is one such peptide sequence which can be used to modify the soluble antigens. The present sequence is tandem HA/ pK peptide conjugate. The modified antigen composition may be used for immunising against, or treating a tumour e.g.

                                                                                                                               The present invention relates to compositions of modified soluble protein antigens capable of eliciting an enhanced in vivo cytotoxic T cell (CTL) response i.e. a major histocompatability complex (MHC) class I molecule response. The protein antigen is modified by the covalent addition of a peptide sequence which facilitate entry of the antigen into antigen presenting cells (APCs). The present sequence is one such peptide sequence which can be used to modify the soluble antigens. The present sequence is peptide HA. The modified antigen composition may be used for immunising against, or treating a tumour e.g. prostate and breast carcinoma or multiple myeloma, or pathogen in mammals.
                                                                                                           Sequence
                                                                                                                                                                                                                                                                  Claim 2; Page 26; 34pp; English.
                                                                                                                                                                                                                                                                                       Antigens modified by the covalent addition of a peptide that facilitates entry into antigen presenting cells, useful for compositions for immunizing against tumors and pathogens -
                                                                                                                                                                                                                                                                                                                                                                 Laus

The arrangment of at least one, pref. three cystein residues at one end of these peptides has been found useful for the fusion activity, for the fusion of the liposome to the target cell membrane. The liposomes produced using these peptides can contain at least one active drug and can be used to target cells infected with cancer

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       CC Peptides AAW34269-W34284 represent novel lipid vesicles with positively CC charged lipid bilayer membranes composed of a cationic and/or CC polycationic lipid and at least one natural or synthetic viral fusion CC peptide integrated in, or covalently linked to, the membrane. Such CC peptides are used as drug delivery ystems, preferably for (non-)specific delivery of genetic material to target cells or tissues, CC particularly for diagnosis, treatment (especially antisense treatment) of cancer, leukaemia and viral infections in humans or animals. Genetic CC material is delivered, without infection, to resting or proliferating CC cells, in vitro or in vivo. When the genetic material is an antisense continuous lipid layer does not leak. The peptides do not need to fuse CC with, or destabilise, plasma membranes in order to enter the cytoplasm, CC since the fusion peptide ensures cell penetration by endocytosis (after Which fusion of the vesicle and endosomal membrane occurs). The genetic CC material thus has a greater chance of reaching the nucleus before it is cefficient than when using liposomes or conventional virosomes, so

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   The present sequence is a crosslinker which is capable of linking to the surface of a novel cationic virosome and is capable of binding polypeptides. The cationic virosome is a lipid bilayer vesicle comprising a membrane with a net positive charge and contains 5-30 weight % based on total lipids, 1,3-dioleoylovy 2-(6-carboxy-spermyl)-propyl-amide (DOSPER), together with other lipids and at least one active fusogenic peptide. The fusogenic peptide is a viral haemagglutinin that causes the vesicle to be internalised by target cells through phagocytosis or endocytosis. The virosome is useful for delivering a desired drug or substance, preferably a nucleic acid, to target cells (resting or proliferating mammallan cells) such as cancer cells, leukaemic cells or virally infected cells in vitro, in diagnostic or medical applications and for the manufacture of medicament for carrying out non-infectious
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   Lipid bilayer vesicle, useful for delivering drugs to target cells such as cancer, leukemic, or virally infected cells, comprises viral glycoproteins in positively charged membrane -
                                                                                                                                                                                                                   Synthetic.

```
A new composition has been developed for transfecting higher eukaryotic CC cells contains: (i) a complex of nucleic acid to be expressed plus a CC suboptimal concentration of one or more cationic lipids, and optionally CC at least one auxiliary lipid; and (ii) the new feature, at least one membrane-active, acidic peptide; where the ratio total positive CC charges: total negative charges in the composition is about 0-3, CC preferably 0-2. The present sequence represents a specifically claimed acidic peptide for use in the composition. The composition is used for CC transfection in vitro, in vivo or ex vivo, particularly for gene CC thrappy. A typical application is production of tumour vaccines from CC autologous cells transfected with a cytokine gene. The acidic peptide CC destabilises the endosomal membrane and significantly increases CC transfection efficiency, e.g. by as much as 1000 times, equivalent to that achieved with the optimal amount of cationic lipid. The acidic peptide also makes the transfection complex less sensitive to serum.
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          Composition containing nucleic acid complexed with cationic lipid and a membrane-active, acidic peptide - used to increase efficiency of transfection by destabilising the endosomal membrane, especially useful for gene therapy

The sequences given in AAR26004-19 are influenza fusion peptides, derived from the influenza virus haemagglutinin gene which were used for the preparation of synthetic membrane vessicles. The arrangment of at least one, pref. three cystein residues at one end of these peptides has been found useful for the fusion activity,
                                                                                                                                        Drug-contg. phospholipid bi:layer vesicle with cell-specific markers on membrane - where markers have at least 90 per cent biological activity, used as pharmaceuticals against e.g. cancer
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               transfer moiety comprising one or more cationic polyamine components bound to the nucleic acid composition. There are several different cationic polyamines that can be used in the complex, one of which contains one of these sequences linked via a bridging group to the main body of the cationic polyamine. The products can be used for delivering therapeutic agents, vaccines, foodstuffs, herbicides, plant growth regulators, insecticides, mittcides, rodenticides, fungicides, parasiticides or nematocides. They can also be used for immunising an individual against a pathogen or for treating an autoimmune disease or hyperproliferating disease. The complexes provide for a high level of transfection and expression of the nucleic acid molecules in target
                                                                                                 Disclosure;

                 CC Peptides AAW34269-W34284 represent novel lipid vesicles with positively CC charged lipid bilayer membranes composed of a cationic and/or polycationic lipid and at least one natural or synthetic viral fusion CC peptide integrated in, or covalently linked to, the membrane. Such CC peptides are used as drug delivery systems, preferably for (non-)specific delivery of genetic material to target cells or tissues, CC particularly for diagnosis, treatment (especially antisense treatment) of cancer, leukaemia and viral infections in humans or animals. Genetic CC material is delivered, without infection, to resting or proliferating CC cells, in vitro or in vivo. When the genetic material is an antisense CC with, or destabilise, plasma membranes in order to enter the cytoplasm, CC with or destabilise, plasma membranes in order to enter the cytoplasm, CC which fusion peptide ensures cell penetration by endocytosis (after CC which fusion of the vesicle and endosomal membrane occurs). The genetic CC material thus has a greater chance of reaching the nucleus before it is degraded or expelled. Transfer of the material is 1000-20000 times more centred when using liposomes or conventional virosomes, so
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   В
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               Š

                                                                                                                                                                                                                                                                                                                                                                                             The present sequence is a crosslinker which is capable of linking to the surface of a novel cationic virosome and is capable of binding polypeptides. The cationic virosome is a lipid bilayer vesicle comprising a membrane with a net positive charge and contains 5-30 weight 8 based on total lipids, 1,3-dioleoyloxy-2-(6-carboxy-spermyl)-propyl-amide (DOSPER), together with other lipids and at least one active fusogenic peptide. The fusogenic peptide is a viral haemaggluthnin that causes the vesicle to be internalised by target cells through phagocytosis or substance, preferably a nucleic acid, to target cells (resting or substance, preferably a nucleic acid, to target cells, leukaemic cells or viral the manufacture of maddical applications and active comment of modifications of modification of modification of modification of modifications of modification of modifications of modifi

                                              transfer molety comprising one or more cationic polyamine components bound to the nucleic acid composition. There are several different cationic polyamines that can be used in the complex, one of which contains one of these sequences linked via a bridging group to the main body of the cationic polyamine. The products can be used for delivering therapeutic agents, vaccines, froodstuffs, herbicides, plant growth regulators, insecticides, mittcides, rodenticides, fungicides, parastiticides or nematocides. They can also be used for immunising an individual against a pathogen or for transfection and expression of the nucleic acid molecules in target
                                                                                                                                                                                                                                         AAR98010-R98041 represent fusogenic peptides derived from spike glycoproteins of enveloped viruses. These fusogenic peptides act as endosome membrane disruption promoting components (EMDPCs). These sequences were used in a transfer moiety which makes up part of the multifunctional molecular complex of the invention. The multifunctional molecular complex of the invention. The multifunctional molecular complex is used for the transfer of a nucleic acid composition and a target cell, and comprises the nucleic acid composition and a
                                                                                                                                                                                                                                                                                                                                                                                                                                                 New complexes for nucleic acid transfer to target cells - comprising a nucleic acid compsn. and a cationic poly:amine with an endosome

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         The invention relates to hybrid polypeptides comprising enhancer peptide sequence linked to core polypeptides. The enhancer polypeptides are derived from various retroviral envelope (g941) protein sequences, especially from HIV-1, HIV-2 and SIV. The enhancer peptides enhance the pharmacokinetic properties such as increasing the half-life of any core polypeptide that they are linked to. The core polypeptides are any polypeptide that may be introduced into a living system and that can function as a pharmacoligically useful peptides are bloactive peptides gelected from a growth factor, cytokine, differentiation factor, interests.

                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    interleukin, interferon, colony stimulating factor, hormone or angiogenic factor. The peptides of the invention can be used for inhibiting viral infection and can be used in anti-fursion and infection and can be used in anti-fursion treatments. Sequences AAY88651-Y90055 represent core polypeptide fragments that can be used in the invention. Some sequences among those indicated also comprise enhancer fragments at terminal ends
                                                                           ABB01088 standard;
                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        A new hybrid polypeptide with enhanced comprises enhancer sequence -

                                              Viral core polypeptide, SEQ ID NO:
                                                                                                                                                                                                                                                                                                                                        The invention relates to isolated analogues of the heptad repeat region peptides DP178 and DP107. DP178 and DP107. correspond to amino acids 638-673 (heptad repeat region HR2) and 558-595 (heptad repeat region HR1) respectively, of HIV-ILAI transmembrane protein gp41. The HR1 and HR2 regions of proteins interact non-covalently with each other and/or with peptides derived from them. This interaction is required for normal infectivity of viruses such as RSV and HIV. The heptad repeat region peptide analogues may be used to inhibit respiratory syncytial virus (RSV) infection in a cell. They may also be used to inhibit HIV infection. The present sequence is a peptide provided in

                                                                                                                                                                                                                                                                           The invention relates to isolated analogues of the heptad repeat region peptides DP178 and DP107. DP178 and DP165. Garcespond to amino acids 638-673 (heptad repeat region HR1) respectively, of HIV-ILAI transmembrane protein gp41. The HR1 and HR2 regions of proteins interact non-covalently with each other and/or with peptides derived from them. This interaction is required for normal infectivity of viruses such as RSV and HIV. The heptad repeat region peptide analogues may be used to inhibit respiratory syncytlal virus (RSV) infection in a cell. They may also be used to inhibit HIV infection. The present sequence is a peptide provided in the percent region.

therapy vectors, allowing these to be endocytosed by GPCR-expressing cells. They can also be used e.g. to treat hypertension (angiotensin-based LD); to increase levels of luteliaising hormone (LH), using LD derived from LH-releasing hormone, or to promote skin tranning (LD based on alpha -melanocyte-stimulating hormone, MSH). The bivalent agonists are administered orally, by injection or topically. Typical doses for skin tanning are 1-4000 (especially 30-100) mu mole/kg systemically or containing are 1-4000 (especially 30-100) mu mole/kg systemically or containing on 1-10 (especially 1) mM. Where both LD are agonists, the bivalent agonist ligands, and where both LD are agonists, the bivalent agonist ligands, and where at least 1 is an antagonist the effect is stimulatory. The bivalent agonists are active at lower concentrations than known agonists so should avoid toxicity problems.
                                                                                                                                                                                                                                               bivalent agonists comprise: (a) two ligand domains (LD), individually agonists or antagonists for GPCR, spaced 40-250 Angstrom apart, and (b) a molecular backbone (MB) covalently bound to LD. The bivalent agonists are useful in human or veterinary medicine as carriers for drugs or gene
                                                                                                                                                                                                                                                                                                               This sequence represents one of two identical chains disulphide bonded to form a bombesin dimer. The invention relates to bivalent agonists, with affinity for at least 1 protein coupled receptor (GPCR). The
                                                                                                                                                                                                                                                                                                                                                                                              Claim
                                                                                                                                                                                                                                                                                                                                                                                                                          Bivalent agonist of G-protein coupled receptors containing two ligand domains - bonded to molecular backbone, for treatment of hypotension, promotion of skin tanning etc., also for delivering drugs and gene therapy vectors to selected cells

A.

The present invention relates to compositions of modified soluble protein antigens capable of eliciting an enhanced in vivo cytotoxic T cell (CTL) response i.e. a major histocompatability complex (MHC) class I molecule response. The protein antigen is modified by the covalent addition of a peptide sequence which facilitate entry of the antigen into antigen presenting cells (APCs). The present sequence is one such peptide sequence which can be used to modify the soluble antigens. The present sequence is peptide by. The modified antigen composition may be used for immunising against, or treating a tumour e.g. prostate and breast carcinoma or multiple myeloma, or pathogen in mammals.

organisation and/or gene transcription. The sequences of the invention are useful in screening assays to identify antagonists and/or agonists that may enhance or block activities mediated by DNA-binding proteins. Blockers of DNA-binding proteins may be useful in treating disorders such as malignant diseases (e.g. cancer), autoimmune disorders (e.g. diabetes mellitus), rheumatic diseases (e.g. rheumatoid arthritis), genetic abnormalities (e.g. cystic fibrosis), infectious diseases (e.g. HIV) and neurological disorders (e.g. Alzheimer's disease). The polynucleotide sequences of the invention may also be used in gene therapy. AAU18154-AAU18281 represent novel DNA-binding

specification,

proteins

The present invention relates to the isolation of novel DNA-binding proceins, and cDNA (AAS29030-AAS29157) and genomic sequences encoding proteins. DNA-binding proteins such as histones, chromo (chromatin organisation modifier) domain proteins, and Y-box binding proteins may contribute to diseases resulting from aberrant DNA proteins may contribute to diseases resulting from aberrant DNA

Nucleic acid molecules encoding human secreted chromosomal binding proteins, used in preventing, treating or ameliorating a disorder, e.g. Alzheimer's and Parkinson's diseases and cancers -
